resulting from disagreement would be resolved. Our basic building block is the disagreement function, which maps each set of feasible outcomes into a disagreement point. Adding this function to the description of a bargaining problem, a weak axiom based on individual rationality leads to a unique solution: the agreement in the shadow of conflict, ASC. This agreement may be construed as the limit of a sequence of partial agreements, each of which is reached as a function of the parties' relative power in the disagreement scenario. As a result, we identify a link between the circumstances of bargaining and the bargaining powers within it.

Key words: Bargaining, conflict, disagreement. *JEL Numbers:* C78, D74.

«The rich get the law passed by means of force and arms or get it accepted by fear to their might, aren't things this way?» Plato, Republic.

1 Introduction

Standard bargaining theory arrives at solutions in two steps. The first step consists in the reduction of a bargaining situation into the confines of a *bargaining problem*, defined by Nash (1950) as the set S of feasible utility allocations and the threat point d . The latter is meant to be the outcome of some (presumably) wasteful interaction that follows disagreement. Thus, different “disagreement games” – reflecting altered distributions of power among the players – are summarized as different threat points. The second step – which has concentrated the efforts of bargaining theory proper so far – consists in selecting a solution to this simplified problem. The solution to this second step is based on either a set of plausible axioms or on the outcome of a posited extensive-form game that is completely independent from the one which determines the disagreement point. This game might admit differential bargaining power among the agents, as in the generalized Nash solution. Our essential point is that current bargaining theory establishes no link between the power of the players in the first step – determining d – and in the second step, when fixing the shares of the surplus over

and above d . Our paper is an attempt at integrating these two steps in a consistent manner.

Specifically, we claim that the differential power of the players in the underlying non-cooperative game supporting the disagreement point also influences the bargaining process itself and, in fact, it actually determines its solution. In order to capture the differential power in the non-cooperative game we need more information on the disagreement game than just the equilibrium payoffs. We need a – reduced-form – description of the disagreement game itself. As it turns out, all the relevant information can be summarized by the specification of how the outcome of conflict, d , varies as a function of the stakes, S . This is the – game-specific – *disagreement function*, $D(\cdot)$, which maps sets of payoffs into the corresponding equilibrium of the disagreement game.¹ An *extended bargaining problem* is thus described by a pair $(S, D(\cdot))$: the set of the payoffs initially available and the disagreement function providing the outcome of disagreement for any subset of these payoffs. We wish to stress that the disagreement function is NOT freely chosen by the modeler, rather it forms part of the description of a bargaining situation and, therefore, it is exogenously given. The main contribution of this paper is to establish the connection between these heretofore neglected conditions that “surround” the actual bargaining and the bargaining solution itself.

The nature of the disagreement game depends on the problem at hand. In some situations, it is so rudimentary that players do not even have a choice over alternative strategies. Consider, for instance, bargaining over the price of an object in the middle of a bazaar. If the players do not reach an agreement, the potential buyer walks out

¹Note that this additional information was already required for the determination of d in the standard context, since the knowledge of the game is necessary to find its equilibrium. Once the game is well defined, it is straightforward to calculate its equilibria under different hypothetical $S' \subseteq S$. As an example, consider the case when disagreement leads to, say, a Prisoners' Dilemma type game, where the payoffs are proportional to some simple function of S' , say the amount of money at stake. Given the scale, all we need to know then, is the unique Nash equilibrium of the basic Prisoners' Dilemma game in order to generate the disagreement payoffs for any $S' \subseteq S$.

and goes to the next shop. Thus, the disagreement payoffs are simply the outside options of the parties. However, such extremely simple situations seem the exception rather than the rule. In the previous case, it is essential that players terminate any future relationship after reaching disagreement. Whenever players do not cease to interact, the disagreement game is necessarily richer. Social relationships are of this type. The fact that we may fail to achieve a particular collective agreement simply means that the future relationship among agents will be non-cooperative. The same can be said of oligopolistic markets, industrial disputes, or simply of individuals litigating over a particular issue of their concern. This is also the case in the international arena, where one cannot modify who are one's neighbors.

For our purposes, the only condition we need the disagreement game/function to satisfy is that disagreement does not result in the loss of the entire surplus. That is, either the surplus should not be fully relationship specific, or upon disagreement the players should continue the interaction and reach a non-negotiated settlement which does not destroy the full surplus. For this class of bargaining situations a simple axiom – essentially positing individual rationality – permits the characterization of a unique and efficient solution: the *agreement in the shadow of conflict*, or ASC. The axiom of the Independence of Individually Irrational Alternatives, IIIA, simply states that the agreement should not depend on the availability of alternatives that are not individually rational – that is, they are dominated by the outcome of the disagreement game for at least one player. This axiom, in principle, would not be stronger than Nash's axiom of Independence of Irrelevant Alternatives (in fact, it requires the solution's independence of fewer alternatives), however, here it is applied in the context of an extended bargaining game, what increases its bite (see below).

The key observation driving our result is that once we eliminate the individually non-rational agreements, the bargaining problem becomes a different one – with a new bargaining set reduced to the remainder. Via the disagreement function, the new bargaining set yields a new threat point as well. Since our axiom applies to all extended bargaining problems, it also applies to this new (continuation) one, and

further reduces the set of feasible agreements. We show that the repeated application of IIIA to the resulting sequence of bargaining games converges to a situation where the disagreement outcome is efficient, thus pinpointing a unique solution.

To fix ideas, consider the simple example of splitting an inheritance of, say, ten euros, between two siblings (who do not care for each other). The siblings can either agree on a particular split at no cost, or disagree and engage in a costly dispute over the money. Suppose that, if they engaged in conflict, in equilibrium seven euros would be wasted (on, say, lawyers' fees), while of the remaining three euros one sibling would expect to obtain two and the other one. This allocation may reflect the fact that, for instance, one's lawyer is "twice" as influential as the other's.² As a result of the expected outcome of conflict, any agreement must give to the siblings at least two and one euros, respectively. Recognizing this, they are willing to get to a partial agreement, which guarantees them these outside payoffs. Consequently, the effective area of dissent shrinks to the remaining seven euros, which are precisely the benefits from cooperation. On the division of these seven euros the siblings may again either agree or disagree and engage in a dispute. In the dispute, say, four euros would be wasted and the strong sibling would obtain two and the weak one. Notice that even if they disagree, both siblings are better off by respecting their partial agreement and restricting the dispute to the distribution of the seven euro surplus. It thus follows that any agreement must give to the siblings at least four and two euros, respectively. This observation generates a new partial agreement. Applying the argument repeatedly, we reach the final agreement, where the ten euros are distributed according to the power of the parties in the conflict game:³ $20/3$ and $10/3$.

²For example, the expected division ruled by the court may be 7:3, but the cost of the better lawyer is 5 while the cost of the worse one is only 2.

³In contrast, both the Nash (1950) and the Kalai-Smorodinsky (1975) solutions would predict that the seven-euro surplus over and above the (total) disagreement point would be brotherly shared by the two players. They would obtain 5.5 and 4.5 euros in total, respectively.

The argument above provides an attractive interpretation of negotiation as a *process*⁴ where, driven by the fear of a conflictual resolution, the parties accept to gradually narrow down the extent of their dissent.⁵ Along each step of this process, it is the relative power of the players, as embodied in the disagreement function, what shapes the solution. We prove that for a very rich class of games, perfectly informed, rational agents will accept to reduce the area of their dissent completely: they will reach an agreement.

We also clarify the connection between the ASC, the generalized Nash and the Rubinstein solutions. Restricting attention to proportional disagreement functions (what corresponds to fixed discount factors in the Rubinstein-type models) and to a simplex as the Pareto frontier, we show that the ASC solution coincides with the asymmetric Nash solution, where the ratio of bargaining weights is equal to the proportion of the disagreement utilities.

The paper is structured as follows. In the next section, we discuss the conceptual forbearers of our approach. In Section 3 we develop our axiomatic theory of bargaining in the shadow of conflict for general environments. We discuss the properties of disagreement functions, present the IIIA axiom, characterize the bargaining solution

⁴This process may be an actual one or just a thought process, which directly leads the players to agreement.

⁵Indeed, we observe that even in the cases in which players do not reach agreement and go into playing the conflict game – think of the extreme case of wars – they do accept restricting its amplitude. Thus, countries accept not to bomb civilian targets or to abstain from the use of particularly harmful weapons. Likewise, plaintiffs may reach a *partial* pre-trial agreement still leaving part of the dispute unresolved. What keeps the conflict from escalation is the separation between the agreement and conflict games: not respecting a (partial) agreement is not a unilateral deviation in the conflict game; instead it is a unilateral deviation provoking a transition to the conflict game. This way such a deviation is observable: the countries foresee each other’s reaction to a unilateral deviation. For example, according to our solution, in a complete information Cournot model, two identical firms would each agree to produce half the monopoly quantity, which is indeed the optimal colluding outcome (for them). The Nash equilibrium would correspond to unrestricted conflict (that is, competition) in this case.

and prove that it is unique. In Section 4 we provide an example for the disagreement game. In Section 5 we analyze the linear model. Finally, we provide a discussion of the related bargaining literature, followed by some concluding remarks.

2 Might and right in social agreements

The view we develop here is to a good extent inspired by Hobbes' theory of social agreements. Well before Economics developed the theory of bargaining, Political Philosophy had addressed the question of social agreements in its inquiry about the foundations of the state. Thomas Hobbes (1588-1679) was possibly the first modern political philosopher who formulated an articulated theory of the *social contract*.⁶ He viewed the possibility of a collective agreement as a case of "conditional cooperation" (in Taylor's, 1987, words), constrained by what individuals can obtain in the state of nature. The state of nature is the outcome that would ensue from a non-cooperative, rule-free interaction among utility maximizing, selfish individuals (Hobbes' *first axiom*). The outcome of this interaction is resource consuming and is governed by the differences in endowments across individuals. His second axiom asserts that there exist agreements that Pareto dominate the allocation achieved under the state of nature. Finally, according to his third axiom, agreements should be conditioned by the allocation resulting in the state of nature: «... *it is a precept, or generall rule of Reason, That every man, ought to endeavour Peace, as farre forth as he has hope of obtaining it; and when he cannot obtain it, that he may seek, and use, all helps, and advantages of Warre*» (Leviathan, 100, as cited in Taylor, 1987, 131). Therefore, in Hobbes' view, social agreements are not the outcome of an idealistic introspection on how things ought to be, but rather the viable outcome of a process conditioned by the might of the parties.

That actual social agreements will, at least partly, reflect the distribution of power is to be expected as long as a social contract is to be found acceptable by all parties.

⁶See Taylor (1987) and Gauthier (1990).

Therefore, and this is one of Hobbes' characteristic themes, we cannot develop a theory of social contracts without reference to the power of the parties in the non-cooperative scenario. The state of nature not only determines the size of the potential surplus to be shared, but also the shares themselves.

It is our opinion that standard bargaining theory has been driven to the use of normative axioms because the description of the bargaining problem was so stylized that there were no bases left for a positive derivation of the corresponding agreement.⁷ We develop a positive theory of agreements, adopting Hobbes' position that takes the initial conditions as given and focuses on *reachable* social agreements, quite independently of the moral judgement they might deserve. We reserve normative considerations for the "state of nature," the initial conditions under which a particular agreement has been reached.⁸ This view is consistent with Roemer's (1996) reservations about the moral content of a bargaining agreement obtained without a prior redistribution of the initial endowments.

We explore whether a solution can be characterized saving on axioms and making a more intensive use of the information contained in the description of the background game. This approach is in line with the growing literature on the explicit modeling of the conflictual resolution of opposing interests. The works by Becker (1983) on pressure groups and Tullock (1980) on rent-seeking, are the predecessors of the more recent papers by Esteban and Ray (1999), Grossman (1991, 1994), Grossman and Kim (1995), Hirshleifer (1991, 1995), Horowitz (1993), and Skaperdas (1992) among

⁷Svejnar (1986), Roemer (1988) and, more recently, Chen and Maskin (1999) have also expressed their reservations about the standard description of a bargaining problem, pointing out that Nash's abstraction might be dispensing with essential information.

⁸Consider the parallel case of assigning the gains from exchange. Economics takes a positive stand and investigates the terms of trade that will actually take place, resulting from different market structures and characteristics of the traders. It does not inquire about which would have been the "fair" terms of trade. The normative valuations are reserved for the comparison of the distribution of the characteristics that condition the trade (distribution of endowments, for instance).

many others.⁹ The common feature of all these models is that the opposition of interests is resolved via conflict. Players expend resources into trying to make their preferred option prevail. The equilibrium outcome entails waste of resources and the particular allocation reached critically depends on what is at stake as well as on the relative power, among other relevant characteristics, of the players. It seems only natural to enquire why there is conflict to start with and whether there exist plausible conflict-avoiding agreements in this scenario.

3 Agreements in the shadow of conflict

Suppose that there are N players, who wish to reach an agreement in $S^0 \in \Sigma$, where Σ is the set of non-empty, convex, compact subsets of the utility¹⁰ space, \mathfrak{R}_+^N . In case of disagreement, during any point of the negotiation, the payoffs are given by (the solution¹¹ to) a disagreement game played for the currently available stakes (some subset of S^0). Even though this game may be elaborate and may depend on a number of parameters, for our purposes the only relevant information is the relationship between the stakes and the outcome. Hence, we posit the existence of a *disagreement function*, $D(\cdot)$, which assigns a disagreement point, d , to every $S \in \Sigma$, (and therefore, to every non-empty, convex, compact subset of S^0). That is, if the set of alternatives currently considered were S , the outcome of disagreement would be

⁹Models of the conflictual resolution of opposing interests have also been developed in areas such as growth, international trade, industrial organization, organizational design, patent races, or economics of litigation, to mention just a few. Conflict models have also been developed for boundedly rational individuals (see, for example, Anderson et al., 1998).

¹⁰Actually, for our analysis it is not necessary that preferences satisfy the von Neumann-Morgenstern axioms. We could directly phrase our model in terms of money, prestige or the like. We elaborate on this issue in the Conclusions.

¹¹This solution maybe a unique Nash (subgame-perfect?) equilibrium, but uniqueness of equilibrium is not necessary. In case of multiplicity, the “disagreement outcome” can be defined as the meet of the utility vectors gained at the different equilibria. In the next section we provide a family of conflict games with unique equilibria.

$d = D(S) \in S$.

It is important to stress that we need not impose any structure on $D(\cdot)$, since it is meant to be a positive description of some real underlying conflict situation and, therefore, it cannot be freely chosen by the modeler. $D(\cdot)$ may depend on additional parameters, especially those related to the players' "strength", which form part of the description of the conflict game.

A *bargaining solution* is a mapping, $f_D: \Sigma \rightarrow \Sigma$, satisfying $f_D(S) \subseteq S$ for all $S \in \Sigma$ and $D(\cdot)$. That is, given $D(\cdot)$, the solution selects a non-empty, convex, compact subset of the alternatives as acceptable.

Define $S_x = \{s \in S | s \geq x\}$. That is, S_x is the subset of S which weakly Pareto dominates x . Note that, if $S \in \Sigma$, then $S_{D(S)} \in \Sigma$ as well.

As long as players act rationally, any solution should weakly Pareto dominate the disagreement outcome, since otherwise at least one player would prefer to provoke disagreement. In other words, from the knowledge that players are rational we can deduce that any agreement on S should be a member of the set S_d . Our only assumption is that any eventual agreement on S should not be altered if we eliminate all the alternatives that cannot be candidate solutions under individual rationality (i.e. the complement of the set S_d in S).

We thus impose the following axiom on the bargaining solution:

Axiom 1 *Independence of Individually Irrational Alternatives (IIIA):*

$$f_D(S) = f_D(S_{D(S)}) \text{ for all } S \in \Sigma.$$

Imposed on a standard bargaining problem, IIIA would simply eliminate the alternatives that do not weakly dominate the disagreement point. However, in our context, IIIA has a recursive effect: once we eliminate the individually irrational alternatives, the application of the disagreement function to the remaining set results, in general, in a different disagreement point than before. Consequently, the axiom applies again, eliminating further possible agreements. In fact, as long as $D(S)$ is

interior to S , the application of IIIA keeps generating new – smaller and smaller – sets of acceptable agreements.

In view of its recursive implications, should we still find IIIA a plausible axiom? We certainly think so. The point of all “irrelevant alternatives” type axioms is to provide some consistency between solutions of the same underlying bargaining situation but with different sets of available agreements. In our view, the appropriate description of the bargaining situation should not be confined to a fixed disagreement point, since the outcome of disagreement is likely to depend on the alternatives available. Therefore, what should be kept fixed when carrying out the “consistency check” is the disagreement function, just as it is done in IIIA. That is, our assumption compares bargaining situations where the same set of players are bargaining in the shadow of the same conflict game but with different sets of feasible utility payoffs.

Our first result shows that the requirement imposed on the solution is not too stringent. To see this, for any $S^0 \in \Sigma$, define the sequences, $d^t = D(S^t)$ and $S^{t+1} = S_{d^t}^t$, $t = 0, 1, 2, \dots$. Note that the sets S^t are non-empty, compact and nested. Therefore, their intersection is uniquely defined and it is non-empty as well. Let us now consider the bargaining solution $f_D^*(S^0) = \bigcap_{t=0}^{\infty} S^t$. This solution satisfies IIIA. To see this, take any $\widehat{S}^0 \in \Sigma$. We have that $f_D^*(\widehat{S}^0) = \bigcap_{t=0}^{\infty} \widehat{S}^t$. At the same time $f_D^*(\widehat{S}_{D(\widehat{S}^0)}^0) = \bigcap_{t=1}^{\infty} \widehat{S}^t$. Since $\widehat{S}_{D(\widehat{S}^0)}^0 \subseteq \widehat{S}^0$, $\bigcap_{t=0}^{\infty} \widehat{S}^t = \bigcap_{t=1}^{\infty} \widehat{S}^t$ and therefore $f_D^*(\widehat{S}^0) = f_D^*(\widehat{S}_{D(\widehat{S}^0)}^0)$. We have thus proven that

Lemma 1 *For any $D(\cdot)$ there exists a bargaining solution consistent with IIIA.*

A further nice property of bargaining solutions satisfying IIIA is that for any bargaining set, the union of all solutions is itself a solution satisfying IIIA, and in fact it is $f_D^*(\cdot)$, the solution displayed in the existence proof above.

Lemma 2 *For any $D(\cdot)$ and for any $S \in \Sigma$, if $f_D(\cdot)$ satisfies IIIA then $f_D(S) \subseteq f_D^*(S) \equiv \bigcap_{t=0}^{\infty} S^t$.*

Proof. Suppose otherwise. Then for some $S^0 \in \Sigma$, $f_D(S^0) \setminus f_D^*(S^0)$ is non-empty. Then since $\lim_{t \rightarrow \infty} S^t = f_D^*(S^0)$, for t large enough it must be the case that $f_D(S^0) \setminus S^t$ is non-empty. However, by IIIA, we have that $f_D(S^0) = f_D(S^t) \subseteq S^t$ for all t . Contradiction. ■

As a result of Lemma 2, we can meaningfully talk about $f_D^*(\cdot)$ as the “maximal” solution satisfying IIIA.

We are now set for the formal definition of our solution concept.

Definition 1 *The agreement in the shadow of conflict solution ($ASC_D(S^0)$) is $\bigcap_{t=0}^{\infty} S^t$, the maximal bargaining solution consistent with IIIA.*

The increase in the informational content of the description of the bargaining problem – together with our axiom – is sufficient to provide us with a unique set of “acceptable” agreements. In general, this set of agreements needs not be a singleton. Whether the predicted outcome is determinate or not, depends on the nature of the disagreement game. We shall now prove that for disagreement games where at least one of the players can obtain a payoff which is “noticeably” superior to the worst possible agreement for them, the above result can be strengthened: the ASC solution singles out a unique, Pareto efficient agreement.

Denote $\max_{z_i} (z \in S_d | z_{-i} = d_{-i})$, the best payoff Player i can get if the rest of the players stay at their status quo payoffs, by $b_i(S_d)$. The formal requirement we need to impose on the generalized bargaining problem, $(S^0, D(\cdot))$, in order to obtain uniqueness, amounts to the following assumption.

Assumption 1 $\exists \epsilon > 0$ such that for all S^t , $t = 1, 2, \dots$, $D_i(S^t) \geq D_i(S^{t-1}) + \epsilon (b_i(S^{t-1}) - D_i(S^{t-1}))$ for some $i \in \{1, 2, \dots, N\}$.

The amount of information contained in the disagreement function depends on whether the players can significantly affect the status quo. If they can’t, the disagreement payoffs convey little, if any, information about the characteristics of the players, so we should not be surprised if they do not pinpoint a unique solution. Assumption

1 is satisfied by non-cooperative games in which there is at least one player that has a choice over a set of possible strategies and that in equilibrium is not indifferent about all of them. Examples of this class of games abound: in pre-trial bargaining the lawyer’s fees are often set as a percentage of the amount under dispute; in collusive agreements in a market setting, even if there is cut-throat Bertrand competition, unless the firms are identical, there is always positive profits for the more efficient firm; in conflict models with endogenous choice of effort there is usually a unique interior Nash equilibrium, etc.¹² Alternatively, if the surplus bargained over is not fully relationship specific, some players must be better off “opting out” than with the status quo, necessarily leading to a higher inside payoff.¹³

Just as with IIIA, we have to ask ourselves the question, whether Assumption 1 remains reasonable when used in a recursive context. The question boils down to the interpretation of disagreement over a set, which Pareto dominates the status quo. What do we mean by disagreement over a set, whose worse element gives the players more utility than the status quo? We believe that this should be understood as a partial agreement: the players agree to distribute some of the surplus in a certain way, thereby reducing the set over which they disagree. As long as this partial agreement is honored even in case of a later break-up, or conflict, the assumption is as valid as when it is made about the original bargaining set.

We can now reap the benefits of Assumption 1:

Proposition 1 *The ASC bargaining solution selects a unique – and therefore efficient¹⁴ – agreement if the generalized bargaining problem satisfies Assumption 1.*

¹²See the next section for an example.

¹³Note that the familiar case of bargaining over the price of an object to be traded, would appear to violate Assumption 1, since the payoffs upon no trade are zero. However, note that in any realistic application, the players are likely to have outside opportunities – ensuring a positive payoff relative to the current status quo – bringing us back to the realm of Assumption 1.

¹⁴By construction, each set S^t contains the points of the weak Pareto frontier of S^0 that dominate $D(S^{t-1})$. Therefore, the point S^* is on the Pareto frontier of S^0 , proving the efficiency of the solution.

Proof. If $ASC_D(S^0)$ is a singleton, then by its maximality it is also unique. Assume it is not a singleton. By Assumption 1, it must be the case that there exists a t high enough, so that $ASC_D(S^0) = \bigcap_{k=0}^{\infty} S^k = S^t$. But then, also by Assumption 1, as S^t is not a singleton, $S^{t+1} \neq S^t$. Contradiction. Therefore, $S^t = ASC_D(S^0)$ must be a singleton. ■

Thus, we have shown that whenever the disagreement functions are informative, a mild axiom about the players' rationality is sufficient to identify a determinate agreement. The essential point is that, by using more information on the player's characteristics, as revealed by the outcomes of the disagreement game, we can dispense with most axioms, except rationality.

4 A model of conflict

It is perhaps useful to consider a concrete family of disagreement games. Esteban and Ray (1999) show that for a generalized version of Tullock's (1980) rent-seeking model (a probabilistic all-pay auction, which captures the idea of wasteful conflict well), there always exists a *unique* Nash equilibrium. Suppose that there is a unit of surplus, to be distributed between two players. If they fail to reach an agreement they will play a (wasteful) non-cooperative game. To be specific, we shall consider the case in which disagreement leads to a *contest game*, where the entire surplus is allocated probabilistically to one of the contestants.

Let p_i denote the probability that player i obtains the surplus. Individuals can influence these win probabilities by contributing effort, r_i . We make the standard assumption that

$$p_i = \frac{\sigma_i r_i}{\sum_j \sigma_j r_j}, \quad (1)$$

where σ_i is the relative power of individual i , so that $\sigma_1 + \sigma_2 = 1$. Power can be construed here as the party's technology of converting effort into what actually matters in the competition.

Individual utility is assumed to be additively separable in consumption and effort. It is linear in consumption and isoelastic in effort.

Thus, the expected utility U_i by player i will be

$$U_i = p_i(r_i, r_j) - \frac{1}{\alpha} r_i^\alpha, i, j = 1, 2. \quad (2)$$

Given the strategy of the other player, r_j , the best response by player i is the effort level r_i that maximizes (2).

A Nash equilibrium of this contest game is a pair (r_i, r_j) such that each level of effort is the best response to the effort contributed by the other agent.

Esteban and Ray (1999) show that as long as $\alpha > 2$, this game has a unique Nash equilibrium. Here, we assume that $\alpha > 2$ indeed. That means, that we can take that unique equilibrium as the predicted outcome of disagreement: the value the *disagreement function*, mentioned in the Introduction, would take.

The first-order condition for a maximum can be written – after some minor manipulation – as

$$p_i p_j = r_i^\alpha \quad i, j = 1, 2. \quad (3)$$

This implies that in a Nash equilibrium $r_i = r_j$ and hence, $p_i = \sigma_i$. Computing the equilibrium utilities, we have that

$$U_i = \sigma_i - \frac{1}{\alpha} \sigma_i \sigma_j = \sigma_i \frac{\alpha - \sigma_j}{\alpha}. \quad (4)$$

Adding over the two players we find that

$$U_1 + U_2 = 1 - \frac{2}{\alpha} \sigma_1 \sigma_2. \quad (5)$$

Therefore, under conflict only a proportion λ of the available money is saved, with

$$\lambda = \frac{\alpha - 2\sigma_1\sigma_2}{\alpha}, \quad (6)$$

and it is distributed in shares

$$\gamma_i = \sigma_i \frac{\alpha - \sigma_j}{\alpha - 2\sigma_i\sigma_j}. \quad (7)$$

Note that, unless one of the parties has all the might, $0 < \lambda < 1$. Therefore, Assumption 1 is satisfied.

5 The linear case

In this section we restrict our attention to bargaining situations where the subproblems considered are affine transformations of the original one. In other words, we assume that the bargaining set has a linear Pareto frontier (corresponding to risk neutrality), and that the disagreement function is homogeneous. These simplifications render the calculation of ASC easy and it also facilitates its comparison with other solutions.

Therefore, in this section we assume that S can be written as $S = \left\{ s \geq 0, \sum_i \beta_i s_i \leq R \right\}$

for some $R > 0$ and some β in the unit simplex.

We shall also focus on the class of disagreement functions that satisfy the following property:

Assumption 2 *The disagreement function $D(\cdot)$ is homogeneous, that is, $D(\alpha + \lambda S) = \alpha + \lambda D(S)$ for all $\alpha \in \mathfrak{R}_+^N$ and all $\lambda > 0$.*¹⁵

We can now easily compute the ASC solution.

Proposition 2 *Let $S^0 = \left\{ s \geq 0, 0 \leq \sum_i \beta_i s_i \leq R \right\}$ and let $D(\cdot)$ satisfy Assumptions 1 and 2. Then, the ASC solution satisfies*

$$\frac{f_i^*(S^0, D)}{f_j^*(S^0, D)} = \frac{D_i(S^0)}{D_j(S^0)} \quad \text{for } i, j = 1, 2, \dots, N.$$

Proof. We know that the solution is $S^* = \lim_{T \rightarrow \infty} \bigcap_{t=0}^T S^t$, where $S^t = \{u \in S^{t-1} \mid u \geq d^{t-1}\}$. Therefore, to obtain S^* we need only to compute $d^* = \lim_{t \rightarrow \infty} d^t$. Note that any set S^t in the sequence satisfies $S^t = d^{t-1} + \lambda^t S^0$, with $\lambda^t = \frac{R - \sum_i d_i^{t-1}}{R}$. By Assumption 2 we have that $d^t = D(S^t) = d^{t-1} + \lambda^t D(S^0)$. Therefore, $d^t = D(S^0) \sum_{r=1}^t \lambda^r$ and the equality in the statement of the Proposition follows immediately. ■

¹⁵It is easy to show that the contest model discussed in the previous section, satisfies that $D(\lambda S) = \lambda D(S)$ whenever the Pareto frontier of the bargaining set is linear.

5.1 A comparison with the Nash Bargaining Solution

Note that while the ASC and the NBS are solutions to qualitatively different bargaining problems, they still are just different ways of approximating how negotiations would end up in a real life situations. Therefore, it is sensible to compare them when the common elements (the bargaining set and the disagreement function evaluated at the bargaining set) coincide. In order to illustrate the differences between the ASC and the NBS, let us examine the case of splitting one euro. The disagreement game is as follows. Whatever the amount of money at stake, x , a fraction β , $0 < \beta < 1$, is lost and of the remainder $(1 - \beta)x$, a fraction α_i goes to each player $i = 1, \dots, N$. It is straightforward that the ASC solution is to give $s_i = \alpha_i$ to each player. Clearly, α_i can be interpreted as the relative *power* of player i and β the degree of inefficiency induced by playing the disagreement game. The ASC solution does not depend on β because the sharing of the surplus of cooperation respects the power of the players as reflected in the disagreement game.

The NBS instead allocates the euro as $s_i^N = (1 - \beta)\alpha_i + \frac{\beta}{N}$. The Nash solution is arrived at by combining the outcome of the disagreement game (biased by the power of the players) and the brotherly sharing of the surplus on the basis of equal division. Parameter β is now the weight assigned by the NBS to the equal sharing rule. The more biased is the disagreement game, the greater is the discrepancy between the Nash and ASC solutions.

Take now the construction of the NBS – that is, a part of the surplus is shared in proportion to the disagreement payoffs and the remainder according to some other sharing rule – but assume that the parameter β is not constrained to coincide with the loss from conflict, rather it can be freely agreed among the players. It is easy to see that the only situation in which the players would agree is when the “other” sharing rule coincides with the one which is proportional to the disagreement payoffs, resulting in the entire surplus being shared in those proportions (irrespective of β).

The example makes it clear that ASC is a solution based on the asymmetric

treatment of the players. Thus, it is natural to explore the relationship between ASC and asymmetric Nash solutions. Recall that the asymmetric Nash solution (see Harsányi and Selten, 1972) results from the constrained maximization of a social welfare function where the individual welfare weights are supposed to embody the differential (bargaining) power of the players: $W(x, d) = \prod_{i=1}^N (x_i - d_i)^{\gamma_i}$. We shall now discuss the relationship between the vector γ and the power of the parties as embodied in the disagreement function.

Recall that the asymmetric Nash solution can be characterized as the point on the Pareto frontier where the pair-wise elasticity of this frontier is equal to the corresponding ratio of the bargaining weights.

We then have the following:

Proposition 3 *When the Pareto frontier of S is the unit simplex and the disagreement function satisfies Assumptions 1 and 2, the bargaining weights corresponding to the ASC solution are $\gamma_i = D_i(S)$, $i = 1, 2$.*

Proof. When the Pareto frontier is the unit simplex, the marginal rate of substitution is 1, everywhere. Consequently the elasticity of the Pareto frontier is equal at every point to the ratio of the utilities at that point. By Proposition 4, this ratio is equal to the ratio of the disagreement utilities. ■

6 A comparative analysis

In this section, we clarify our theory by contrasting it to the most related literature.

i) *Endogenous determination of the disagreement point.*

In his 1953 paper, Nash proposed a generalization of his original model of 1950. In this game, known as the “variable threat” model of bargaining, the players choose threats before the actual bargaining phase, of which they serve as the disagreement point. At first blush, our model may seem just like Nash’s one, with a specific, well-motivated threat game (like Anbarci et al. 2002). Actually, however, our contribution

goes well beyond that. There are two important differences between the models that we would like to underline:

a) Nash needs to employ an “umpire” to oblige the players to carry out their threats (in case of disagreement). We do without a $n + 1^{st}$ party. The underlying reason for this is quite relevant. Nash thinks of the threat phase as one preceding the Nash bargaining game. Therefore, this phase has no interpretation on its own, it is simply a – perhaps realistic – way to make the bargaining game more detailed. In contrast, we think of our conflict subgame as one posterior to bargaining. By invoking sequential rationality, we can then analyze the players’ optimal behavior in that subgame without any additional ommitment device. Apart from the obvious difference in philosophy, the technical difference is also apparent, since in Nash’s game by a well-chosen threat (which she would prefer not to carry out) a player can improve her share, without her bluff ever being called. Thus, even if we used our conflict game as the threat game, the equilibria would differ, since the players, in general, would not use a threat that forms part of an equilibrium of the conflict game.

b) When Nash’s players generate a disagreement point, he considers the bargaining problem properly defined and proceeds to its solution (according to his 1950 paper). In contrast, we argue that they have simply arrived at a new bargaining situation, where they might wish to employ different threats than before. To put it another way: while in the Nash model the demand phase depends on the outcome of the threat phase, in our model the conflict game is supposed to depend on the demands made (when they are not compatible).

ii) *Step-by-step resolution.*

Kalai (1977) introduced the axiom of decomposability. This assumption requires that if we break up the set of available agreements, S , into two subsets, X and Y , then using the solution of (either) one of these as a partial agreement to subsequently bargain over the rest, $(S - f(X, d)) \cap \mathfrak{R}_+^N$, should give the same result as applying the solution directly. Note that Kalai’s model agrees with ours in the idea that partial agreements are only renegotiated if this yields a Pareto improvement. On the other

hand, Kalai does not propose a well-defined solution: he only establishes that the solution should be “proportional,” without identifying what should these proportions be. In addition, Kalai’s model has two caveats, first pointed out by Ponsati and Watson (1997). The first of these is that when agreeing on the first sub-problem, the bargainers of Kalai are not supposed to take into account the effect of today’s agreement on tomorrow’s one. This is not true in our model. Second, there seems to be an inconsistency between the assumption that the agreement on the first subproblem is binding, but at the same time can be renegotiated –since the second sub-problem is not $S \setminus X = Y$ but $(S - f(X, d)) \cap \mathfrak{R}_+^N$. In our model, however, these two sets coincide so we avoid any confusion.

Wiener and Winter (1999) (see O’Neill et al., 2004 for the published version) propose a solution for bargaining problems where the feasible set is exogenously divided up into smaller pieces. Their solution is equivalent to agreeing step-by-step on each “crumb” according to the Nash solution, using the result of the previous step as the new disagreement point. This procedure is similar to ours, but we use the disagreement function to determine the new status quo and we do not need the arbitrary division.

Fearon (1996) proposes a model with flow payoffs where the current distribution of the assets determines the current power in case of (costly) conflict. Assuming one-sided offers, he obtains a unique path of gradually increasing demand.

iii) *Bargaining under the threat of some outside enforcement mechanism.*

This topic has been extensively dealt with in the applied literature (pre-trial negotiations, strikes, arbitration etc.). Perhaps, the piece closest to our approach is Powell (1996). Powell sets up a non-cooperative bargaining game where the players can choose to force a (probabilistic) settlement at some cost. The important difference with respect to our approach is that, in his model, forcing the settlement is equivalent to taking an outside option. However, outside options do not determine, in general, the outcome of a bargaining game. Therefore, Powell needs to rely on the solution to the bargaining game, which would come about in the absence of outside

options. In our case, in contrast, the solution of the game cannot be dissociated from the underlying conflict situation.

iv) *Recursive solutions.*

We are not the first ones to use a recursive application of some rule in bargaining theory. Let us mention just a couple. Raiffa (1953) proposes a method where the players first pocket half of their most preferred allocation, then half of their most preferred allocation in the remainder... etc. While in (its recursive) structure his procedure is very much like ours, the important difference is that he has no justification other than some vague consideration of “fairness” for the fifty percent rule. van Damme (1986) considers a recursivity axiom, which imposes that if the players are making demands according to some individual theories, then in every step of the iteration, as a function of these demands some subset of S is to be discarded, and the negotiation resumed. Technically, the IIIA assumption is very similar, with the important difference that we only invoke individual rationality for discarding “irrelevant alternatives.”

v) *Disagreement modelled as a non-cooperative game.*

Lundberg and Pollak (1993) replace divorce by a non-cooperative equilibrium within marriage, as the disagreement point in a model of marital bargaining. While they implicitly recognize that the forces determining the threat point are the same ones that influence the bargaining process, they do not make this connection explicit, and simply use the Nash solution.

vi) *Endogenous bargaining power.*

Spindler (1974, 1976) proposed a definition of bargaining power which is not fixed, rather it is a function of the agreement considered (and of the status quo). Then the solution can be calculated as the one which equates these endogenous bargaining powers. While his method is very different from ours, it shares the idea of trying to read more out of the bargaining situation than Nash’s bargaining set.

7 Concluding remarks

In this paper we have presented a new approach to the theory of negotiation and have introduced the corresponding agreement concept. The cornerstone of our theory is the more efficient use of information that was already necessary for the standard theory: the description of the non-cooperative resolution of conflict. Indeed, we use not only the utility allocation in a particular equilibrium (the disagreement point), but we make full use of the primitives behind this equilibrium. In fact, we have shown that – provided it is non-trivial – the disagreement function contains sufficient information to derive a unique agreement when coupled with a mild generalization of individual rationality.

We consider our theory to be complementary to the one based on time preferences. In scenarios where delay costs (and the risk of breakdown) are negligible with respect to the stakes of negotiation, like political disputes; or where disagreement leads into conflict which generates inefficiencies that are not related to delay, our approach seems to be more appropriate. In addition, the ASC solution yields a unique solution for an arbitrary number of negotiators, while the alternating-offers models usually generate multiple equilibria for more than two players.

Our theory carries with it a conceptual novelty as well. This insight relates to the interpretation of the terms: *agreement* and *disagreement*. Recall that the general idea of offer-counteroffer models is that disagreement is temporary – in the sense that the rejection of an offer does not end the negotiation – and that agreement is total – in the sense that at each point in time the players are either in agreement or not, no intermediate possibility is considered. Instead, we make the “dual” assumption: we posit that disagreement is final but possibly partial, while agreements can be temporary, and therefore partial as well. That is, we allow for the possibility that the players agree on the sharing of part of the surplus and either postpone agreement or disagree on the rest. The important observation is that the fact that they did not get to full agreement is not interpreted as a complete failure of the negotiation:

the partial agreement can be implemented and the extent (and the efficiency cost) of disagreement is reduced.

To appreciate the degree of the meta-similarity of the dual approaches, note that our enrichment of the bargaining problem with the disagreement function merely corresponds to the incorporation of an exogenous cost of disagreement – over the surplus remaining, conditional on any partial agreement. This is completely parallel to the case where the description of the bargaining problem is augmented with the exogenous parameters of the cost of (temporary) disagreement to each party – following any length of past disagreement. Similarly, our ruling out of a trivial disagreement game corresponds to Rubinstein’s ruling out perfectly patient players. Finally, in both cases the sequential story behind the solution is not meant to be actually followed in real time. Rational, fully informed agents will immediately identify which is the unique solution.

Finally, we should emphasize that we have presented our model based on cardinal preferences only to minimize our departure from standard theory. It is easy to see that we need not restrict attention to the utility space in order to derive our solution. Any underlying space of bargaining outcomes, together with a complete preference relation, would suffice. In other words, our theory is one based on ordinal preferences, an elusive¹⁶ goal for solutions to the standard bargaining problem.
